Chapter 2

Algorithm Analysis

- An algorithm is a clearly specified set of simple instructions to be followed to solve a problem.
- Algorithm analysis is the amount of computer memory and time needed to run a program (algorithm)

We use two approaches to determine it:

- performance analysis
- performance measurement

Space complexity: the amount of memory a program needs to run to completion

Time complexity: the amount of time a program needs to run to completion

2.1 Space Complexity

1)components:

- instruction space
- data space (space needed for constants,simple variables,component variables)
- environment stack space (to save information needed to resume execution of partially completed functions)

2.1 Space Complexity

two parts:

a fixed part—include space for instructions,simple variables,fixed-size component variables,constants

a variable part—include space for component variables,dynamical allocated space,recursion stack

2.1 Space Complexity

2)example:

- Sequential Search

```
public  static int SequentialSearch( int [ ] a , int x )
{   int i;
    for(i=0; i<a.length &&a[i]!=x; i++)   ;
    if(i= = a.length) return –1;
    return i;
}
```

2.1 Space Complexity

Total data space:

12 bytes : x,i,a[i],0,-1,a.length

each of them cost 2 bytes

S(n)=0

2.1 Space Complexity

- Recursive code to add a[0:n-1]

```
public static float Rsum(float[ ] a, int n)
{ if ( n>0 )
      return Rsum(a, n-1) + a[n-1];
   return 0;
 }
```

2.1 Space Complexity

Recursion stack space:

formal parameters : a (2 byte), n(2 byte)

return address(2 byte)

Depth of recursion: n+1

$$S_{Rsum}(n)=6(n+1)$$

2.2 Time complexity

The time taken by a program p is T(p)

T(p)=compile time+run time

The compile time does not depend on the instance characteristics

The run time is denoted by t_p(instance characteristics)

1)operation counts

identify one or more key operations and determine the number of times these are performed

2.2 Time Complexity

Example 1

- finding the largest number in a[0:n-1]

```
public static int  Max( int [ ]a, int n)
{//locate the largest element in a[0:n-1]
  int pos=0;
  for(int i=1;i<n;i++)
      if(a[pos]<a[i])  pos=i;
  return pos;
}
```

compare time : n-1

2.2 Time Complexity

Example 2

- selection sort

0	1	2	3	4	5
21	25	49	25^*	16	08
08	25	49	25^*	16	21
08	16	49	25^*	25	21
08	16	21	25^*	25	49
08	16	21	25^*	25	49
08	16	21	25^*	25	49

2.2 Time Complexity

```
public static void SelectionSort( int [ ] a, int n)
  {//sort the n number in a[0:n-1].
     for(int size=n; size>1; size--)
       { int j=Max(a,size);
          swap(a[j],a[size-1]);
        }
   }
```

2.2 Time Complexity

Analysis of selection sort

1)each invocation Max(a,size)results in size-1 comparisons, so the total number of comparisons is :

$$n-1+n-2+\ldots\ldots+3+2+1=(n-1)*n/2$$

2)the number of element move is 3(n-1)

2.2 Time Complexity

Example 3

- bubble sort

8 25 32 15 20 38 46 54 67

```
public static void Bubble( int [ ] a , int n)
  {//Bubble largest element in a[0:n-1] to right
     for(int i=0; i<n-1; i++)
         if(a[i]>a[i+1])swap(a[i],a[i+1]);
   }
```

2.2 Time Complexity

```
public static void BubbleSort( int [ ] a, int n)
 {  //Sort a[0:n-1] using a bubble sort
    for(int i=n ;i>1; i--)
       Bubble(a,i);
 }
```

2.2 Time Complexity

Analysis of bubble sort

the number of element comparisons is (n-1)*n/2,as for selection sort

2.2 Time Complexity

Example 4

- Rank sort

```
r:  0   2    1    4    3
     0   1    2    3    4
a:  8  25  16  30  28
```

```
public static void Rank( int [ ] a, int n, int [ ] r)
  {//Rank the n elements a[0:n-1]
      for(int i=0;i<n;i++)
          r[i]=0;
      for(int i=1;i<n;i++)
         for(int j=0;j<i;j++)
             if(a[j]<=a[i]) r[i]++;
             else r[j]++;
  }
```

2.2 Time Complexity

```
public static void Rearrange( int [ ]a, int n, int[ ] r)
 {//In-place rearrangement into sorted order
     for(int i=0;i<n;i++)
         while(r[i]!=i)
        {   int t=r[i];
             swap(a[i],a[t]);
             swap(r[i],r[t]);
        }
  }
```

2.2 Time Complexity

Analysis of rank sort

the number of element comparison is :

(n-1)*n/2

the number of element swap is 2n

2.2 Time Complexity

Best,Worst,and Average Operation Counts

- The average operation count is often quite difficult to determine.
- As a result,we limit our analysis to determining the best and worst counts.

2.2 Time Complexity

Example 5

- Sequential Search

```
public static int SequentialSearch( int [ ] a,  int x, int n)
{  int i;
   for(i=0;i<n&&a[i]!=x;i++) ;
   if(i= =n)return-1;
   return i;
 }
```

2.2 Time Complexity

Analysis of Sequential Search

- For successful searches,the best comparison count is one, the worst is n.
- The average count for a successful search is:

$$(1/n)\sum_{i=1}^{n} i=(n+1)/2$$

2.2 Time Complexity

Example 6

- insertion sort

```
    0  1  2  3  4  5  6
a:  8  3  2  5  9  1  6
    3  8  2  5  9  1  6
    2  3  8  5  9  1  6
    2  3  5  8  9  1  6
    1  2  3  5  8  9  6
    1  2  3  5  6  8  9
```

```
public static void Insert( int [ ] a , int n, int x)
 {//Insert x into the sorted array a[0:n-1]
    int i;
    for(i=n-1; i>=0&&x<a[i]; i--)
        a[i+1]=a[i];
     a[i+1]=x;
  }
```

2.2 Time Complexity

```
 public static void InsertionSort( int [ ] a,  int n)
{    for(int i=0; i<n; i++)
     {    int t = a[i];
          Insert(a,i,t);
     }
}
```

2.2 Time Complexity

Another version of insertion sort

```
public static void InsertionSort( int [ ]a, int n)
{  for(int i=0;i<n;i++)
   { //insert a[i] into a[0:n-1]
        int t=a[i];
        int j;
        for(j=i-1; j>=0&&t<a[j]; j--)
             a[j+1]=a[j];
        a[j+1]=t;
    }
 }
```

2.2 Time Complexity

Analysis of insertion sort

both version perform the same number of comparisons.

the best case is

$n-1$

move number is

$2*(n-1)$

the worst case is

$(n-1)*n/2$,

move number is

$(1+2)+(2+2)+\ldots\ldots+(n-2+2)+(n-1+2) =$

$n*(n-1)/2+2*(n-1)=(n^2+3n-4)/2$

2.2 Time Complexity

2) Step counts

- to account for the time spent in all parts of the program/function.
- we create a global variable count to determine the number of steps

2.2 Time Complexity

Counting step

```
public static Comparable Sum( Comparable[ ] a,  int n)
 {  Comparable tsum = 0 ;
    count++;
    for (int i = 0 ; i<n ; i++)
      { count++;
        tsum += a[i] ;
        count++;
       }
     count++;
     count++;   return  tsum;
  }
```

2n+3 step

2.2 Time Complexity

3).Asymptotic Notation(O, Ω, θ,o):

describes the behavior of the time or space complexity for large instance characteristics.

2.2 Time Complexity

I)Big Oh Notation(O): provide a upper bound for the function f.

Definition:

$f(n)=O(g(n))$ iff positive constant c and n_0 exist such that $f(n)<=cg(n)$ for all n, $n>=n_0$

For example:

linear function $f(n)=3n+2$. when $n>=2, 3n+2<=3n+n=4n$, so $f(n)=O(n)$;

Quadratic function $O(n^2)$,exponential functionO(2^n), constant functionO(c)

2.2 Time Complexity

Example 1: Selection sort

	Frequency
a[0],a[1],…,a[n-1]	
for (int i=0 ; i < n-1 ; i++)	n
{ int k= i;	$n-1$
for (int j=i+1; j<n ; j++)	$(n^2+n-2)/2$
if (a[j]<a[k]) k=j;	$<=(n^2-n)/2$
int temp=a[i]; a[i]=a[k]; a[k]=temp;	$3(n-1)$
}	

$T(n) = n^2+5*n-5$

$n\text{--->}\infty \quad T(n)/n^2\text{----->}constants(1)$

$T(n) = O(n^2)$

2.2 Time Complexity

Example 2: Binary Search

```
     0   1  2  3  4  5  6   7    8
 a: -1  0  1  3  4  6  8  10  12         x = 6
public static int binarySearch( Comparable [ ] a, Comparable x )
{   int low = 0, high = a.length - 1;
    while( low <= high )
    {   int mid = ( low + high ) / 2;
        if(  a[ mid ].compareTo( x ) < 0 )
            low = mid + 1;
        else if( a[mid ].compareTo( x ) > 0 )
                high = mid – 1;
             else  return mid;
     }
     return NOT-FOUND;
}
```

最好: 一次　最坏: $\log_2 n$　　平均 $O(\log_2 n)$

2.2 Time Complexity

Example 3: MAXIMUM SUBSEQUNCE SUM PROBLEM

给定整数$a_1,a_2,\ldots,a_n$(可能有负数），求$\sum_{k=i}^{j} a_k$的最大值。

如果所有整数均为负数，则最大子序列和为0。

	1	2	3	4	5	6
a:	-2	11	-4	13	-5	-2

Algorithm 1: merely exhaustively tries all possibilities

```
public static int maxSubSum1( int [ ] a )
{   int maxSum = 0;
    for ( int i = 0; i < a.length; i++ )
       for ( int j = i; j < a.length; j++ )
       {    int thisSum = 0;
            for ( int k = i; k <= j; k++ )
                thisSum += a[k];
             if ( thisSum > maxSum )
                 maxSum = thisSum;
        }
    return maxSum;
 }
```

2.2 Time Complexity

- analysis
  - $O(N^3)$

2.2 Time Complexity

Algorithm 2:

```
public static int maxSubSum2( int [ ] a )
{   int maxSum = 0;
    for( int i = 0; i < a.length; i++ )
    {    int thisSum = 0;
         for ( int j = i; j < a.length; j++ )
         {   thisSum += a[j];
             if ( thisSum > maxSum )
                 maxSum = thisSum;
          }
     }
     return maxSum;
}
```

$O(N^2)$

2.2 Time Complexity

Algorithm 3: recursive and relatively complicated O(Nlog N)

分治法(divide-and-conquer)

分阶段：把问题分成两个大致相等的子问题，然后递归地对它们求解。

治阶段： 将两个子问题的解合并到一起，可能再做些少量的附加工作，最后得到整个问题的解。

example:

4 -3 5 -2 -1 2 6 -2

a_1 a_2 a_3 a_4 a_5 a_6 a_7 a_8

a_1----a_4 的最大子序列和为6, a_1----a_3

a_5----a_8 的最大子序列和为8, a_6----a_7

横跨这两部分且通过中间的最大和为：

a_1-----a_3+a_4 ＋ a_5+ a_6---a_7 = 11

2.2 Time Complexity

```
private static int maxSumRec( int [ ] a, int left, int right )
{   if ( left = = right )
        if ( a[ left ] > 0 )
            return a[ left ];
        else  return 0;
    int center = ( left + right ) / 2;
    int maxLeftSum = maxSumRec( a, left, center );
    int maxRightSum = maxSumRec( a, center + 1, right );
    int maxLeftBorderSum = 0, leftBorderSum = 0;
    for ( int i = center; i >= left; i-- )
    {   leftBorderSum += a[i];
        if ( leftBordersum > maxLeftBorderSum )
            maxLeftBorderSum = leftBorderSum;
    }
```

2.2 Time Complexity

```
        int maxRightBorderSum = 0,  rightBorderSum = 0;
        for ( int i = center + 1; i <= right; i++ )
        {   rightBorderSum += a[ i ] ;
            if ( rightBorderSum > maxRightBorderSum )
                maxRightBorderSum  =  rightBorderSum;
         }
        return max3( maxLeftSum, maxRightSun,
                           maxLeftBorderSum + maxRightBorderSum );
    }

public static int maxSubSum3( int [ ] a )
{    return maxSumRec( a, 0, a.length – 1 );
}
```

analysis:

O(N logN)

2.2 Time Complexity

Example 4: Euclid’s Algorithm

计算最大公因数(greatest common divisor)。 通过辗转相除。

例如 50, 15 的最大公因数是5

```
public static long gcd( long m, long n )
{   while( n != 0 )
    {   long rem = m % n;
        m = n;
        n = rem;
    }
    return m;
}
```

O(log N)

2.2 Time Complexity

II).Omega Notation (Ω): is the lower bound analog of the big Oh notation,permits us to bound the value f from below.

Definition:

f(n)= Ω(g(n)) iff positive constant c and n_0 exist such that f(n)>=cg(n) for all n, n>=n_0

2.2 Time Complexity

III).Theta Notation(θ): is used when the function f can be bounded both from above and below by the same function g.

Definition :

f(n)= θ(g(n)) iff positive constants c_1 and c_2 and a n_0 exist such that $c_1g(n)<=f(n)<=c_2g(n)$ for all n, $n>=n_0$

space and time complexity: use Big Oh Notation

Chapter 2

Exercises:

1. Find the complexity of the function used to find the kth smallest integer in an unordered array of integers

```
int selectkth ( int a[], int k, int n){
    int i, j, mini, temp;
    for  ( i = 0; i < k; i++){
        mini = i;
        for ( j = i+1; j < n; j++)
            if  ( a[j] < a[mini])
                mini = j;
        tmp = a[i];
        a[i] = a[mini];
        a[mini] = tmp;
    }
    return a[k-1];
}
```

Chapter 2

2. Find the computational complexity for the following four loops:

```
c. for (cnt3=0, i =1; i<=n; i*=2)
        for (j=1; j<=n; j++)
            cnt3++;
d. for (cnt4=0, i=1; i<=n; i*=2)
        for (j=1; j<=i; j++)
            cnt4++;
```

Chapter 2

3. For each of the following two program fragments:
   Give an analysis of the running time(Big-Oh will do)

```
1)  sum = 0;
    for( i = 0; i < n; i++ )
       for( j = 0; j <i*i; j++ )
          for( k = 0; k <j; k++ )
               sum++;
2)  sum = 0;
     for( i = 1; i < n; i++ )
        for( j = 0; j < i*i; j++ )
           if( j % i == 0 )
               for( k = 0; k < j; k++ )
                     sum++;
```

Chapter 2

4. 设n为正整数，分析下列各程序段中加下划线的语句的执行次数。

```
1) for (int i = 1; i <= n;  i++)
      for (int j = 1; j<=n; j++)
      {   c[i][j] = 0.0;
          for ( int k = 1; k <= n; k++)
             c[i][j] = c[i][j]+a[i][k]*b[k][j];
      }
2)  x = 0; y = 0;
    for (int i = 1; i <= n; i++)
      for (int j = 1; j <= i; j++)
        for (int k = 1; k <= j; k++)
          x = x+y;
3)  int x = 91;  int y = 100;
      while(y>0)
      {   if(x>100) { x -= 10;  y--; }
          else x++;
      }
```
